

Meal worms fruit

Diet

The sugar glider eats meal worms, all kinds of fruit, and veggies. Those are the food that I know of.

Characteristics

The sugar glider has big black eyes, a bushy tail, and they are tan with black and brown stripes. So it can blend in with its ecosystem they can also be white, and they can also glide in the wind. Its Scientific name is *Petaurus breviceps*.

SUGAR GLIDER

By Elena

Ecosystem

Sugar gliders live in the west Australian rainforest. They live in trees, and they nest in holes in the trees. Ecosystem means a community of organisms living together. They live in a wet-land rainforest, some other animals that live there are the eastern yellow robin, kangaroo, and the eastern koala.

Adaptation

Sugar glider have many adaptation such as gliding, big eyes so they can look out for their enemy's in the dark. They also have a grooming claw which is just two claws in one direction, which helps them groom their self.

Human Interaction

People do interact with sugar glider. People even have them as pets mainly because they are cute, cuddly, and very interesting. They are beneficial in their ecosystem because if they were extinct their food (meal worms and fruit) would increase a lot because that is what they eat.
