

Adaptations

Its adaptations are very good because their eyes can see very well and they have strong bones for running. Another adaptation is its ears. They have good hearing and they can hear predators.

WILD BUNNY

By Andi

Ecosystem

Where they live???

Bunnies live all over the world. They even live in the deserts, but they mostly live in forests and grassy land where there sometimes mostly are. Baby bunnies and adults feed on carrots, leaves, grass, vegeta. A ecosystem is a place were living and non living things can interact with each other.

Its predators are lions, dogs, hawks , eagles, mountain lions, and other predators that are bigger than them. Not all larger animals than it but the ones I listed were its predators.

Characteristics

The types of bunnies are cotton tails, jack rabbits, floppy eared, and straight eared,

A wild baby bunny gets to leave the nest after at least 4 to 7 weeks or it takes about 2 months sometimes to leave its mom. The father of the bunny or any other bunny cant see they are babies. The mom will kill them even with house bunnies you are not aloud to see them. A wild mother bunny always makes sure to have her nests blend in with the ground when she goes to get food so her babies wont die.babies need milk from there mom at age 1 and it takes about three weeks till it dosen't need

*****Human Interactions*****

Some people eat rabbits but not a lot .Most people just have them on their farm or they keep them as pets. Bunnies are also not endangered but people cut off their foot when they are dead because they think they are lucky. Have you ever heard of a lucky rabbit foot? It's weird mostly Indians thought they were lucky . People also cut off their tail for things like scarfs,
